

shipyards was 0.34 and 0.49 parts per million, respectively.

Laboratory analysis of total and dissolved fractions (passing 0.45 micron filter) of field samples confirmed that the highest percentage of metal contamination in wastewater was contributed by suspended solids. Dissolved metal contamination was relatively low. Based on the average values for total and dissolved metals in boatyard wastewater, analysis showed that suspended solids accounted for 97 percent of the copper, 94 percent of the lead and 83 percent of the zinc. A similar analysis for shipyard wastewater indicated that suspended solids accounted for 94 percent of the copper, 80 percent of the lead and 91 percent of the zinc.

Chemical oxygen demand (COD) was used as a rough measure of the biodegradable organic content in the wastewater. The survey data showed the average values of COD in hull-washing wastewater to be of the same magnitude as COD in a dilute sewage

wastewater. This COD concentration can produce low oxygen conditions and decay odors and gases in the wastewater that is not treated. This result was confirmed in the field. As with metals, COD is contributed mostly by wastewater suspended solids, comprising 80 percent of shipyard wastewater COD and 90 percent of boatyard wastewater COD.

Two particle-size/settling experiments were performed on boatyard and shipyard composite samples. The experiments related particle size, as a function of settling time, to the concentration of metals in wastewater. Figure 2-1 illustrates that particles less than 60 microns in diameter contribute 80 to 90 percent of the copper contamination in suspended solids. Particles less than 20 microns in diameter contribute about 50 percent of the copper. This finding is important since particles of this size settle out of solution slowly, making simple settling an ineffective means of treatment.

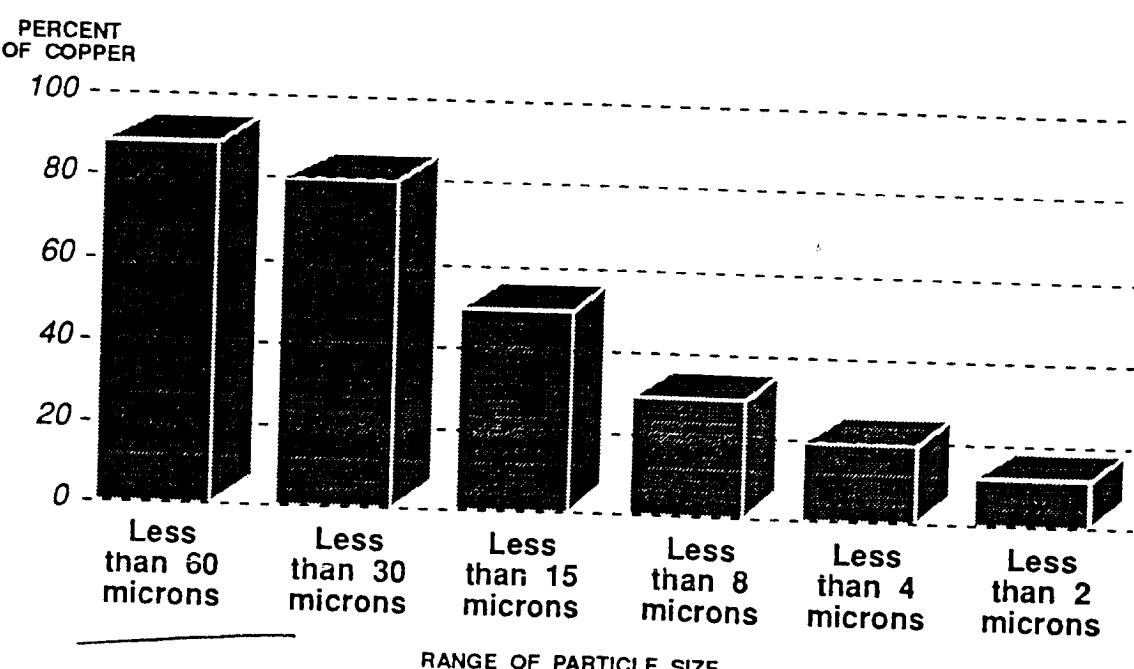

Figure 2-1: Percent of Copper Versus Particle Size – Boatyard Pressure-washing Wastewater Sample
